6	run	11
7	outlook	12

1 introduction

These instructions[5] follow the configuration and build of a Linux-based operating system for *Raspberry π - 4 - model B*[7] with *Yocto*[2]. Find project overview in [6].

The *operating system* (OS) build is done in four steps and instructions are organized in four corresponding sections as follows.

- section 2 get *metadata*
- section 3 configure OS build
- section 4 build OS *image*
- section 5 copy *image* to *SD* card

Section 6 is dedicated to post-install issues like the configuration of the WiFi interface from the command line.

2 download

Metadata is a set of instructions to build targets. It is organized in *recipe* files with the *.bb* suffix. Further there are *class* files with the suffix *.bbclass* with information shared between *recipes*. Finally, there are configuration files with the extension *.conf*. These define configuration variables to control the build process. *Metadata* is organized in *layers*. Layers logically separate information of a project. *OpenEmbedded*[1] defines the following layer types.

- base layer
base *metadata* for the build
- machine aka *board support package* (BSP) layer
hardware (HW) support
- distribution layer
policy configuration
- *software* (SW) layer
additional SW
- miscellaneous layer
for layers that do not fall in upper categories

The complete list of *github* SW *metadata* repositories used in this project includes *Yocto* layers, the *Raspberry π - 4 - model B* BSP layer, a SW layer with custom recipes, and the build configuration itself. Please refer [6] for details.

It is up to users to decide where to download *metadata*. It is a good idea to have all layer sub-directories in one location. In these instructions this is referred as <layer-directory>. Once you have it created execute next lines to get layer *metadata*.

```
git clone -b kirkstone \
git@github.com:yoctoproject/poky.git \
<layer-directory>
```

```
git clone -b kirkstone \
git@github.com:openembedded/meta-openembedded.git \
<layer-directory>
```

```
git clone -b kirkstone \
git@github.com:agherzan/meta-raspberrypi \
<layer-directory>/rpi
```

```
git clone git@github.com:kaloyanski/meta-thc.git \
<layer-directory>/thc/meta-thc
```

The second directory to create is the <build-directory> and I suggest that this one is not inside the <layer-directory> to not mix *data* and *metadata*. Further, to get the project build configuration use the command that follows.

```
git clone git@github.com:TripleHelixConsulting/rpicnf.
<build-directory>/conf
```

3 configuration

After the last command from the previous section there should be two files in <build-directory>/conf, namely *local.conf* and *bblayers.conf*.

The path to Yocto layers is specified in *bblayers.conf*. Layer locations are wrong because most probably your <layer-directory>

is not */home/yocto/layer*. Change this to correspond layers system path.

The build configuration is in *local.conf*. This should work as it is. Variables in this file control the build. No doubt, the most important is *MACHINE*, set to *raspberrypi4-64*. You may want to change this value only if you build an [OS](#) for a different [HW](#). Another important directive is *IMAGE_FSTYPES*. Here I have removed archived *images* that I do not need to decrease the built time and added the *wic* format to have an *image* file ready to be copied to the *SD* card immediately after the build. Further there are many directives not covered in these instructions. Please refer *bitbake* documentation for details. It is not always easy to understand the meaning and the relations between different directives. What is more, *bitbake* syntax is pretty complicated. In short, your life can easily become unbearable if the build configuration is too long.

In the main build configuration, apart from *Dear ImGui* and *GLFW*, I have added the following packages;

- *os – release*
[OS](#) identification
- *Dropbear*
Compact *secure shell* ([SSH](#)) server[4]
- *dhcpcd*
dynamic host configuration protocol ([DHCP](#)) client[8]
- *thcp*
[OS](#) post-configuration scripts

3.1 layers

Here is a list of *Yocto* layers. The project reference distribution is *poky*.

- *meta*
user-space data and standard licenses
- *meta – poky*
Yocto reference distribution policy
- *meta – raspberrypi*
This[3] is the general [HW](#) specific [BSP](#) overlay for the *RaspberryPi* device. The core [BSP](#) part of *meta – raspberrypi* works with different *OpenEmbedded/ Yocto* distributions and layer stacks. In short, the recipes to build the kernel and kernel modules are in this layer. For details see the package *linux-raspberrypi*. In addition, here is the [HW](#) specific firmware. By chance, the build configuration corresponds the specific [HW](#), in this case *Raspberry π - 4 - model B*.
- *meta – thc*
I have introduced a new *Yocto* [SW](#) layer to control the build of *Dear ImGui* and *GLFW*. As long as the source codes have a standard build configuration, the *bitbake* recipes are straightforward. Both instructions inherit *cmake*.

4 build

Yocto provides a list of image types. For obvious reasons, I have chosen *core-image-x11*^[2] - a very basic X11 image with a terminal.

The primary build tool of *OpenEmbedded* based projects, such as the *Yocto* project, *bitbake*, works in the <build-directory>. Here is a list of the most important sub-directory names by default. These are configurable but usually there is no need to change their default names.

- <build-directory>/conf - build (*local.conf*) and layer (*bblayers.conf*) configuration files
- <build-directory>/downloads - downloaded source code archives, usually fetched from github.com
- <build-directory>/tmp/work - working directory where source code is extracted, configured, compiled and installed
- <build-directory>/tmp/deploy/ipk - final [SW](#) packages in *ipk* format
- <build-directory>/tmp/deploy/images/raspberrypi4-64 - boot files, compiled kernels and [OS images](#).

Keeping this in mind, type following commands to build the [OS image](#).

```
source <layer-directory>/poky oe-init-build-env <build-directory>
bitbake core-image-x11
```

The first command is needed to initialise the environment. The second one gonna do the actual build. Be patient because, unless your

task	description
do_fetch	fetch the source code
do_unpack	unpack the source code
do_patch	apply patches to the source
do_configure	source configuration
do_compile	compile the source code
do_install	copy files to the holding area
do_package	analyse holding area
do_package_write_ipk	create <i>ipk</i> package
do_package_qa	quality checks on the package

Table 1: A list of packages in *core-image-x11-raspberrypi4-64*

host machine is a supercomputer, this will take hours. Find a list of tasks performed by *bitbake* for a typical [SW](#) package in Table 1.

5 install

The [OS](#) includes a kernel *ARM*, 64 *bit* boot executable *image* of 23MB, a *Raspberry π - 4 - model B* configuration of Linux 5.15. The total size of kernel modules is 21MB. Happily this kernel release has a *long – term support* ([LTS](#)).

Yocto provides multiple package and *image* formats. Further, different ways exist to install *images* on *SD* card. The result is an [OS](#) with two partitions - */root* and */boot*. There are not *swap* and *home* partitions. I recommend the classic command-line tool *dd* to copy data. It works fine with different *image* formats like *rpi – sdimg*, *hddimg* and *wic*. The last format is recommended. Find the card device name, usually */dev/sda*, unmount it with *umount* if mounted, and do copy data with a simple command

dd if=core-image-x11-raspberrypi4-64.wic of=/dev/sda status=progre

note 1: run this command in *<build-directory>/tmp/deploy/images/raspb*
64

note 2: run this command with *root* privileges

note 3: be careful to not specify the device name of your hard drive
(see note 2)

The transfer is going to take a while. Once it is over, put the card
in you *Raspberry π - 4 - model B* and turn it on. That's it.

6 run

Connected embedded systems can communicate to one another and to cloud-based *platform-as-a-service* (PaaS) solutions. In addition, a remote control may be required. An SSH server is a standard solution for both problems.

Wireless connection is established via classic command-line tools like *ip*, *iw*, *dhcpcd*, and *wpa_supplicant*. Custom shell scripts are installed in */usr/bin*, as well as a running *graphical user interface* (GUI) example to demonstrate the usage of the *Dear ImGui* library. Once an *internet protocol* (IP) address is assigned, the SSH server by *Dropbear* allows for a secured remote login, remote control and file transfer.

7 outlook

This reports the progress in the development of a custom Linux-based OS for *Raspberry π - 4 - model B*^[7]. The kernel version of this embedded OS is Linux release 5.15. An example GUI application using the *Dear ImGui* library is built as a part of the OS image. In addition, an SSH server provides remote connection, data transfer and device control. As the OS is now functional, performance and real-time tests are ongoing.

acronyms

BSP *board support package*

SSH *secure shell*

GUI *graphical user interface*

SW *software*

HW *hardware*

OS *operating system*

DHCP *dynamic host configuration protocol*

IP *internet protocol*

PaaS *platform-as-a-service*

LTS *long – term support*
